(54) Title: A METHOD OF AND APPARATUS FOR COMPUTER SECURITY USING A TRANSMITTING LOCATION DEVICE

(57) Abstract

A method and apparatus enhance computer security based on pre-registration and tracking of a computer user's location. A location device accompanies an individual attempting to log-in to a computer network from a location distant to the network. When the location device is activated, it transmits a location signal which is received by the computer network. The network then determines from the location signal where the individual is located during the log-in process. If the individual is at a pre-defined physical location, the computer grants access; otherwise, access is denied.

**A METHOD OF AND APPARATUS FOR COMPUTER SECURITY USING  
5 A TRANSMITTING LOCATION DEVICE**

**BACKGROUND OF THE INVENTION**

**FIELD OF THE INVENTION**

10 The present invention relates to a method of and apparatus for computer security using a transmitting location device, and, more particularly, to a method of and apparatus for adding an additional layer of computer security based on registration and tracking of the computer user's location.

15 **DESCRIPTION OF RELATED ART**

The increasing use of remote access, that is the use of a computer or other device to communicate with a computer network from a location distant from the network, has enabled individuals who otherwise do not have authorized access to the computer network to none-the-less violate computer security from afar. The 20 ability of computer hackers to infiltrate a computer network from a distant location can be a serious threat to a company's well-being. This threat is especially serious for companies which have an ever increasing reliance on a workforce who tele-commute to work from home everyday. Thus knowing where an individual is when they attempt to gain entry to the computer network would be an important 25 aspect of computer security.

Position detection for locating individuals, devices, and vehicles has been accomplished. For example, U.S. Patent No. 5,689,269, issued November 18, 1997 to Norris, relates to an apparatus and method for determining the position of a first device relative to the position of a second device using the Global Positioning 30 System (GPS). The first device, with a person or object to be located, transmits telemetry position data to the second device after first receiving a GPS signal and determining its own location using that GPS signal. The second device receives

2

the telemetry position data from the first device and calculates a relative distance between the two devices. The calculation performed by the second device is based on the telemetry position data received from the first device and knowledge about its own position determined from GPS signals that it has previously received. The 5 second device is also capable of determining direction and difference in elevation between the first and second devices.

Further, U.S. Patent No. 5,550,551, issued August 27, 1996 to Alesio, relates to a position monitoring system and method particularly applicable to vehicle monitoring. When activated, a position detector mounted on the vehicle 10 uses GPS signals to determine vehicle location information. On a pre-determined basis, the position detector periodically updates the vehicle location information and transmits a location information signal based on the vehicle's location to a remote dispatch center. The dispatch center receives the transmitted location information signal from the position detector, determines the vehicle location, and 15 relays that information to an appropriate law enforcement agency.

Yet another example, U.S. Patent No. 5,389,934, issued February 14, 1995 to Kass, relates to a portable system for locating a person, vehicle or object. The system uses a GPS unit and a piece of cellular telephone equipment. The system's locating function is first activated by receipt of a telephone call on 20 the piece of cellular telephone equipment. Upon this activation, the system then determines its own location via the GPS unit and responds to the call with a voice message stating its current location. The person, vehicle or object may then be retrieved.

As can be seen, however, while the ability to accurately locate a 25 person, device or vehicle exists, this ability has not been applied to help with computer security. As the threat of a breach of computer security from afar still exists, and in fact seems to be increasing, there still remains a need for a method of enhancing computer security based on detection of location.

30 **SUMMARY OF THE INVENTION**

Accordingly, in response the present invention, as embodied and broadly described herein, provides a method of and apparatus for adding an

additional layer of security to the computer log-in process based on registration and detection of location. Thus, an individual who wishes to log-in to a computer system must not only be an authorized user of the system, but must also be attempting to log-in from a pre-registered and authorized location or zone.

5 Proper location is checked through the use of a transmitting location device. When an individual who is an authorized user of a computer network desires to access that network from a location distant to the network, a location device is activated. Once activated, the location device will transmit a location signal to the computer network.

10 An additional layer of security is thus added through the use of the transmitting location device. This is accomplished when the individual is logging-in to the network. Once the locating device has been activated and is transmitting a locating signal, the computer network will receive that locating signal and determine where the individual is as they are attempting to log-in. The computer network will then match that determined location against a list of pre-registered 15 locations. If the individual is in fact located at a location that has been pre-registered, the computer network will allow access using both the location information and the standard security measures (e.g. ID and password). Thus not only must the person be an authorized user (which can be determined by the ID and 20 passcode, *inter alia*), but the location must be a pre-authorized and pre-registered location.

Further, the additional security may be added to the on-going session as well. As the individual is logged-on to the network, the network may reactivate the location device to periodically check the individual's location. 25 Periodic updates allow the computer network to ensure that the individual is still at and/or in the pre-registered location or zone, and that a proper location signal is being received.

The present invention, including its features and advantages, will become more apparent from the following detailed description with reference to 30 the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates a flow chart of a method of enhancing computer security using a transmitting location device in which the location device transmits a location signal during an attempt to log-in to a secure computer network, 5 according to an embodiment of the present invention.

Figure 2 illustrates a schematic of an apparatus by which transmission of the location signal from the location device to the computer network can be carried out, according to an embodiment of the present invention.

10 DETAILED DESCRIPTION

Figures 1 and 2 show a method and an apparatus for adding an additional layer of security to a computer log-in process based upon a pre-registration operation and a subsequent detection of a computer user's location. Thus the location from which the computer user attempts to log-in, and from which 15 he or she continues to work, becomes an additional element by which computer security may be maintained. If the individual using the computer logs-in from a pre-registered location, and the central computer recognizes that location as an authorized location, log-in to the computer network is permitted. However, if the identified location is determined not to be an authorized location, log-in is not 20 permitted. Subsequent updates of the computer user's location can also be used to ensure that the user is still in the authorized location. Thus if the individual is subsequently determined to be outside of the pre-registered location, access to the computer network can be terminated.

An individual who will have need of logging-in to a computer 25 network from a location outside of the immediate area of the computer network will be required to pre-register the location (or locations) from which he or she shall be logging-in. A central computer will then consider each pre-registered location as an authorized location for that individual. In essence, then, the location is keyed to that individual and is the only location from which the individual may 30 log-in and continue to work. Approval of the location by the central computer may be dependent upon any number of pre-set criteria. Further, ultimate approval may reside with the appropriate company personnel. It is to be understood, then, that

the location approval process may be established and administered in any manner which the company (and/or individuals) using the present invention approves. It is not to be limited to simply the embodiment herein described, and is only of importance in ensuring that the registered locations are in fact pre-approved.

5        The actual locations being pre-registered by the computer user may be a single place or a broader area. For instance, an individual may want to pre-register his or her home, and may also want to pre-register the area which follows a route to and from work. Such a registration scheme thus allows the individual to work from home and also to work while en route to or from work. It is to be 10      understood, of course, that the number of locations which each individual may be allowed to register can be pre-set. Further, registration of places or areas may be keyed to specific days or to specific times of the day. An individual may want to register his or her home only for authorized use during the weekends, when that individual knows he or she may need to work from home. The route to and from 15      work may be registered for those times of the day which the user knows he or she is more likely to be commuting. Even further, if the user knows that he or she will be traveling away on business, the user may pre-register the location to which he or she will be traveling, and may register for only those days on which he or she expects to actually be there.

20       Detection of the individual's actual location when he or she attempts to log-in to a computer network is accomplished by activation and tracking of a locating device which the individual shall have with them. The individual may either be personally carrying the locating device, or it may be attached to, or an integral part of, the computer terminal (whether portable or fixed) 25      from which the individual is logging-in. The locating device itself is a transmitting and receiving device capable of both sending and receiving a location signal. The transmission of the locating signal may, of course, be continuous or intermittent, and may be digital and/or analog in nature.

30       Activation and initial tracking of the locating device is triggered by the central computer of the network at the time of log-in. Further explanation of the activation and tracking sequence will be given below with reference to the drawings.

Referring to Figure 1, a central computer may have associated with it a network, which from the central computer's perspective is co-located with that computer. In step 100 an individual who will have a need to log-in to the central computer from a site remote from or not co-located with the central computer will 5 pre-register one or more locations from which he or she will want to log-in. Registration of such log-in sites will preferably occur at the location of the central computer using a controller that interfaces with the central computer. Alternatively, such registration may be accomplished from a secure remote site. Once the sites for remote access have been input to the central computer, in step 10 110 an approval process for each location input will be implemented. As stated above, there may be various approval processes. Preferably someone having a position of authority and/or responsibility for overseeing computer security will give final approval for remote access sites. Further, each site may be designated as "dormant" until an attempt to log-in is made from that remote site. Once a log-in 15 occurs from a site, the site's status may be changed to "active" and notification of the log-in and use of the site may be sent to the appropriate persons (i.e., persons in charge of computer security), and perhaps including the site's registrant. Further, an "active" site which has not been used for a pre-set period of time may be changed back to a "dormant" state. Such classification of sites can be helpful in 20 keeping track of which sites have and/or have not been used and may further help to maintain security.

Once a log-in location has been pre-registered and approved, an individual may access the central computer from that location by logging-in. In step 120 the individual seeking remote access to the central computer and network will log-in in the normally accepted fashion. For instance, the individual will 25 establish contact with the central computer and can present his or her identifying code and password. It is to be understood, of course, that the present invention can be used with any type of log-in procedure, and is not limited to a log-in procedure which uses an identifier and passcode. Further, it should be noted that once a 30 location is registered and approved, as in steps 100 and 110 explained above, the individual need not register that location each time he or she wishes to log-in from that location. On the contrary, the central computer can store the registered and

approved location for future use. In other words, steps 100 and 110 need not be repeated each time the method of the present invention is to be utilized. It may be, however, that re-registration of locations will be required on the basis of some pre-selected criteria, and thus steps 100 and 110 will need to be repeated. For instance, 5 re-registration of a location may be required after a certain period of time has elapsed, after a certain number of log-ins from that location have occurred, after a certain total number of system log-ins have occurred, or any other similar criterion.

In step 130, once the central computer is contacted by an attempted log-in, the central computer will identify on the basis of at least one parameter who 10 the individual attempting to log-in purports to be and will activate the location device associated with that individual. In other words, if the central computer determines that the parameters of the identifier and password submitted in the log-in are associated with a computer user named "Tom", then the computer will activate the location device associated with "Tom" and which "Tom" carries 15 around with him. It is to be understood, of course, that identification of the location device to be activated can be accomplished by any method and on the basis of any parameters which assure that the proper location device will be activated. For instance, parameters used in the log-in and subsequent activation may be on the basis of voice recognition, body heat signature, retinal scan, 20 fingerprint scan, and/or visual observation, etc.

Further, actual activation of the location device can be carried out by any method, as long as the locating device is functionally activated. For instance, activation can be accomplished through radio signals, electrical signals, and/or infrared signals. Preferably the location device will be activated through a 25 medium separate from that which the individual is using to log-in to the central computer. That is, for example, if the individual attempting to log-in is doing so over the Internet, the locating device can be activated through the use of satellite relays.

Upon activation, in step 140, the locating device transmits a 30 location signal. Transmission of the location signal can be by any medium which ensures that the location signal is received by the central computer. For example, the location signal can be transmitted via airwave and relayed by satellite, or

through land-line using the Internet as a relay. The location signal itself can be any type of signal which is capable of carrying the location data and of being transmitted and received. For instance the signal can be radio wave, infrared, or even microwave. Preferably the location signal is broadcast as a radio wave in 5 either a digital or analog format.

In step 150, the broadcast location signal is received by the central computer and a determination of the location of the locating device is made. In order to make the determination, the location signal may act as a homing beacon or 10 may contain location data (coordinates). If the location signal acts as a homing beacon for the location of the location device, the central computer can determine the location of the locating device. If the locating signal contains location data, that is, the actual location (coordinates) of the locating device, then the location device itself can determine its own location. Either way, position detection will 15 need to be accomplished and it is acceptable that any such position detection method or system be utilized. Preferably, the Global Positioning System is used.

Upon a determination of the location of the locating device, in step 160 the central computer decides if the locating device's location is at, or within a pre-determined proximity of, a pre-registered location. If the location is 20 determined to be valid, log-in will be completed. If the location is not valid, log-in will be terminated. This decision step, then, determines whether access will be granted or denied. If the log-in is allowed to be completed, in step 170 the individual logging-in may then access the data files of the central computer. If the 25 log-in is not allowed, in step 180 the connection is terminated and the central computer can generate appropriate messages to the appropriate parties that an unauthorized log-in was attempted.

In the case where the log-in is allowed because the locating device was determined to be at a pre-registered location, periodic updates of the location of the locating device may be accomplished. This ensures that the locating device stays with the individual who has logged-in, and can also act as a way of checking 30 the original determination of the location of the locating device. Further, if any discrepancies occur in the subsequent updates, the central computer can terminate or restrict access. Lastly, an initial log-in from an authorized site can be used to

fine-tune the location's coordinates, if necessary, so that the system can be more accurate.

It should be noted that the central computer may also at any time send a message to the individual identified in step 130 that he or she has been identified as attempting to log-in and/or has been granted access to log-in. Thus if the individual identified in step 130 is at a pre-registered location, but is in fact not logging-in to the central computer, that individual can notify the appropriate personnel and access to the unauthorized individual in fact logging-in can be denied and/or terminated. Messages may be sent in any fashion which will reach the authorized individual identified in step 130. For instance, a message may be sent via telephone, pager, priority e-mail, etc.

Referring to Figure 2, transmission of the location signal is shown. In this example, the central computer 1 communicates with remote computer 2 via communication medium 4, and with location device 3 via communication medium 6. Thus, when an individual attempts to log-in to the central computer 1 using remote computer 2, the central computer 1 sends an activation signal by communication medium 6 to the location device 3. Communication medium 6 uses satellite system 5 for relay of communication. In response, location device 3 sends location signal 7 via communication medium 6 to central computer 1.

It should be noted that other information can be sent along with the location signal. For instance, information which might be sent might include a "time stamp". Such a "time stamp" could be utilized as an assurance that the location signal is being sent from the location indicated by it. The central computer could be synchronized to the GPS atomic clock and determinations of how long the location signal took to transmit could be made. Also, for instance, a passcode for the location device could be sent. A separate passcode for the location device would ensure that the proper location device was transmitting the location signal.

Thus, as can be seen from the foregoing description, an additional layer of computer security can be added to present computer security systems through the use of the present invention. Further, implementation of the present invention would require only nominal system adjustments.

10

In the foregoing description, the method and apparatus of the present invention have been described with reference to a specific example. It is to be understood and expected that variations in the principles of the method and apparatus herein disclosed may be made by one skilled in the art and it is intended that such modifications, changes, and substitutions are to be included within the scope of the present invention as set forth in the appended claims. The specification and the drawings are accordingly to be regarded in an illustrative rather than in a restrictive sense.

**Claims:**

1. A method for enhancing computer security using a location device, comprising the steps of:
  - 5 registering at least one remote log-in location for a computer network;
  - registering a log-in contact to the computer network;
  - commanding activation of the location device upon establishment of the log-in contact;
  - 10 receiving a location signal from the location device;
  - determining a location of the location device on the basis of the received location signal; and
  - determining whether the location of the location device is an authorized location with reference to the registered information that identifies the at least one authorized remote log-in location.
2. The method according to claim 1, further comprising the step of:approving the registration of the at least one remote log-in location.
- 20 3. The method according to claim 1, further comprising the step of:identifying the location device to be activated upon at least one parameter contained in the log-in contact.
4. The method according to claim 1, further comprising the step of:determining an update of the location of the location device.
- 25 5. The method according to claim 1, further comprising the step of:sending a message to an individual to whom the location device is identified as belonging.
- 30 6. The method according to claim 1, wherein activation of the location device is accomplished by radio wave.

7. The method according to claim 1, wherein the transmitted location signal may contain a plurality of data.
- 5 8. The method according to claim 7, wherein the plurality of data are location coordinates derived from a Global Positioning System.
9. The method according to claim 1, wherein the transmitted location signal contains a "time stamp".
- 10 10. The method according to claim 1, wherein access to the computer network is granted if the location of the location device matches the at least one remote registered log-in location.
- 15 11. The method according to claim 1, wherein access to the computer network is denied if the location of the location device does not match the at least one remote registered log-in location.
12. A method for enhancing computer security using a location device, comprising the steps of:
  - 20 storing information identifying at least one authorized remote log-in location for log-in to a computer;
  - establishing a log-in contact with the computer;
  - activating transmission of a locating signal from the location device
- 25 upon the log-in contact;
  - determining a location of the location device on the basis of the locating signal; and
  - determining whether the location of the locating device corresponds to the at least one remote log-in location.
- 30 13. The method according to claim 12, further comprising the step of:

13

securing authorization for the storing of the at least one remote log-

in location.

14. The method according to claim 12, further comprising the step of:

identifying the location device from which the location signal is to

5 be activated upon at least one parameter contained in the log-in contact.

15. The method according to claim 12, further comprising the step of:

determining an update of the location of the location device.

10 16. The method according to claim 12, further comprising the step of:

sending a message to an individual to whom the location device is  
identified as belonging.

17. The method according to claim 12, wherein activation of the location device is

15 accomplished by radio wave.

18. The method according to claim 12, wherein the transmitted location signal

may contain a plurality of data.

20 19. The method according to claim 18, wherein the plurality of data are location  
coordinates derived from a Global Positioning System.

20. The method according to claim 12, wherein the transmitted location signal

contains a "time stamp".

25

21. The method according to claim 12, wherein computer access is granted if  
the location of the location device matches the at least one authorized remote log-  
in location.

30

22. The method according to claim 12, wherein computer access is denied if the  
location of the location device does not match the at least one authorized remote  
log-in location.

23. A method for enhancing computer security using a location device, comprising the steps of:

receiving a log-in contact;

5 commanding activation of the location device upon receipt of the log-in contact;

determining a location of the location device on the basis of a received location signal; and

10 determining whether the location of the location device corresponds to an authorized remote log-in location.

24. The method according to claim 23, further comprising the step of:

storing information identifying at least one authorized remote log-in location for log-in to a computer.

15 25. The method according to claim 24, further comprising the step of:

securing authorization for the storing of the at least one remote log-in location.

20 26. The method according to claim 23, further comprising the step of:

identifying the location device to be activated upon at least one parameter contained in the log-in contact.

27. The method according to claim 23, further comprising the step of:

25 determining an update of the location of the location device.

28. The method according to claim 23, further comprising the step of:

sending a message to an individual to whom the location device is identified as belonging.

30 29. The method according to claim 23, wherein activation of the location device is accomplished by radio wave.

30. The method according to claim 23, wherein the transmitted location signal may contain a plurality of data.

5 31. The method according to claim 30, wherein the plurality of data are location coordinates derived from a Global Positioning System.

32. The method according to claim 23, wherein the transmitted location signal contains a "time stamp".

10 33. The method according to claim 23, wherein computer access is granted if the location of the location device matches the authorized remote log-in location.

15 34. The method according to claim 23, wherein computer access is denied if the location of the location device does not match the authorized remote log-in location.

35. An apparatus for enhancing computer security using a location device, comprising:

20 a central computer;  
means for receiving a location signal sent from the location device to the central computer, the location signal containing at least a location of the location device,  
wherein access of the central computer is determined on the basis of  
25 the location of the location device matching a pre-registered access location.

36. The apparatus according to claim 35, further comprising:

means for determining the location of the locating device.

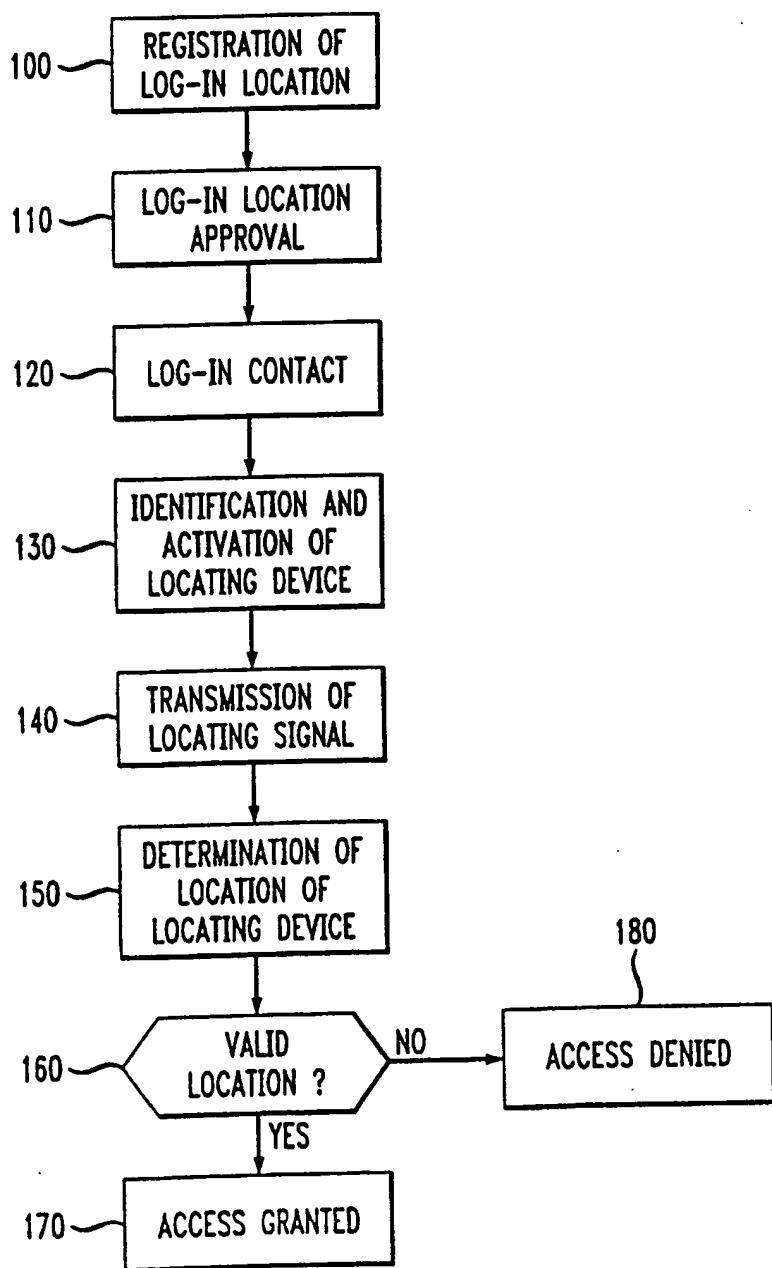

30 37. The apparatus according to claim 36, further comprising:  
a means for communicating between the central computer and a  
remote station.

38. An apparatus for enhancing computer security using a location device, comprising:

- a memory storing at least one authorized remote log-in location
- 5 information;
- a means for allowing a remote log-in contact;
- an activator activating transmission of a location signal from the
- location device;
- a receiver receiving the transmission of the location signal;
- 10 a means for determining a location of the location device on the basis of the transmitted location signal;
- a central computer which determines whether the location of the location device is an authorized location with reference to the stored at least one authorized remote log-in location information.
